

PROJECT TITLE: Evaluation of Continuous Spring Wheat Cropping

PROJECT LEADERS: Jerald W. Bergman, Superintendent, MSU Eastern Agricultural Research Center, Sidney, Montana / Director, NDSU Williston Research Extension Center, Williston, North Dakota

Joyce L. A. Eckhoff, Research Agronomist, MSU Eastern Agricultural Research Center, Sidney, Montana

OBJECTIVES: To determine the feasibility of continuous spring wheat cropping of small grains on dryland when the best-known methods of weed control, fertilizer practices, and other management practices are applied in conjunction with tall wheatgrass barriers. In evaluating tall wheatgrass barriers for continuous spring wheat cropping, the following factors will be documented each year:

1. Crop yield
2. Disease problems associated with continuous cropping
3. Insect problems associated with continuous cropping
4. Tillage problems associated with continuous cropping
5. Weed problems associated with continuous cropping

MATERIALS AND METHODS:

The tall wheatgrass barriers eliminated from this study in 1998 were first established in the summer of 1965 as part of another experiment. As originally planned, the experiment contained 2-row grass barriers with a distance of 42 inches between the grass rows. Four of the barrier strips had inside crop dimensions of 30' by 265'. Three other barriers were of 60' by 265' inside dimensions. For check purposes, an exterior area without grass barriers was provided for in the experiment.

During the 1966-71 crop years, the grass barrier system was cropped each year to either spring or winter wheat. Data was collected on the efficiency of the barriers in trapping snow, preventing soil erosion, and affecting temperature relations over the crop. No fertilizer treatments were applied to the site and no program of controlling annual weeds was instituted. By 1971, the fertility status of the soil had declined to a low level and such annual weeds as wild oats, green foxtail, and yellow foxtail infested the land to a moderately serious degree. Beginning in 1971, an attempt to control these weed populations with herbicides was initiated. Safflower was grown in the barrier system in 1972, but thereafter spring wheat was continuously cropped in the barrier system utilizing effective herbicides and fertilizer. The 30 ft. barriers were eliminated in the fall of 1979 to provide two additional 60 ft. barriers for further continuously cropped studies under no-till and till-and plant conditions. The decision to eliminate the 30 ft. barriers was based on our research results indicating the 30 ft. barriers were too narrow to compensate for yield loss due to land removed from crop production. In 1998, the 60 ft. tall wheatgrass barriers were eliminated. The decision to eliminate the 60 ft. barriers was based on previous results indicating the barriers only compensated for yield loss due to land removed from crop production on dry years when the yield was less than 20 bushels per acre and because of volunteer tall wheatgrass problems in the wheat associated with the tall wheatgrass of the barrier strips. Three of the barrier strips removed were tilled and three of the barrier strips were killed with Roundup herbicide without any tillage.

MATERIALS AND METHODS FOR THE 2000 SEASON:

No tillage was performed on the plots in the fall of 1999 and the stubble was allowed to stand over winter to collect snow. All the plots were sprayed with Roundup herbicide at the rate of 2 quarts per acre on April 12, 2000 to control volunteer tall wheatgrass and emerging weeds.

On April 19th, the plots scheduled for tillage were worked twice with a tandem disc, except the summer fallow plot, which was triple K'd twice. On April 19th, the no-till plots were seeded to Reeder spring wheat using a Versatile Noble No. 2000 no-till double disc drill with leading coulters and 9-inch row spacing.

The tilled plots were also seeded on April 19th using the Versatile Noble No. 2000 double disc drill with 9-inch row spacing. For tilled and no-till plots, Reeder spring wheat was seeded at the rate of 78 pounds/acre and 80 pounds of 18-46-0 was applied through the drill. Additionally, 35 pounds nitrogen per acre was applied on March 27, 2000 in the form of liquid nitrogen 28-0-0.

The type of tillage and planting for the various plots were as follows:

OPEN FIELD STUBBLE - CONTINUOUS CROP

- Plot A - no-till and no-till planting
- Plot B - spring till and seeding
- Plot C - no-till and no-till planting
- Plot D - no-till and no-till planting
- Plot E - spring till and seeding
- Plot F - spring till and seeding
(40 ft. barrier for this plot only)
- Plot G - no-till and no-till planting
- Plot H - spring till and seeding

SUMMER FALLOW - (WHEAT-FALLOW) ROTATION

- Plot I - spring till and seeding on fallow
- Plot J - summer fallow

On May 19th, the plots were sprayed with 2.0 pints Bronate/acre for broadleaf weed control. The plots were also sprayed with 1.0 quart/acre of Roundup on October 2nd to control after-harvest weeds.

RESULTS AND DISCUSSION:

Precipitation as rain or snow occurred at this site during the October 1999 through September 2000 period as follows:

<u>Month and Year</u>	<u>Inches of Moisture</u>
October 1999	0.17
November 1999	0.07
December 1999	0.40
January 2000	0.25
February 2000	0.43
March 2000	0.21
April 2000	0.61
May 2000	3.34
June 2000	1.48
July 2000	4.43
August 2000	0.63
September 2000	<u>1.91</u>
Total	13.93

All of the plots in the study were harvested on August 11, 2000. Grain samples were obtained for test weight and protein analyses.

CONTINUOUS CROPPING RESULTS FROM 2000

	Method of Seeding	Test Weight Lbs/Bu	Grain Protein %	Yield Bu/Acre
1. Continuous Crop				
Plot A	no-till	63.5	13.4	33.1
Plot B	till	63.5	12.2	35.9
Plot C	no-till	63.5	13.4	25.4
Plot D	no-till	63.5	13.7	33.9
Plot E	till	63.5	14.3	34.2
Plot F	till	63.5	13.5	32.8
Plot G	no-till	63.5	12.8	21.8
Plot H	till	63.0	13.2	26.5
2. Summer Fallow				
Plot I	till	63.0	15.0	47.0

On continuous wheat cropping in 2000, tilled and planted plots averaged 32.4 bushels per acre with 13.3 percent protein whereas no-till plots averaged 28.6 bushels per acre with 13.3 percent protein. Open field stubble continuous wheat produced an average yield of 30.5 bushels per acre with 13.2 percent protein, whereas the wheat on summer fallow produced a yield of 47.0 bushels per acre with 15.0 percent protein.

The lower yields on no-till plots compared to tilled plots are attributed to wild oats and volunteer wheatgrass infestations from the tall wheatgrass barrier and its spread into the no-till plots. The applications of one quart of Roundup in the springs of 1993, 1994 and 1995 about two weeks prior to seeding failed to control the volunteer wheatgrass. Two quarts per acre of Roundup spring applied in 1996, 1997, 1998, 1999 and 2000 for volunteer wheatgrass control has provided only fair-good control. The barriers were eliminated in 1998. The incidence of *Pyrenophora trichostoma* (tan spot) and *Septoria* was also most pronounced in the continuous wheat no-till plots, moderate in the continuous wheat tilled plots with a light to moderate level in the wheat on fallow plot. The principal weeds in 2000 were Russian thistle, kochia, wild oats, and volunteer wheatgrass.

Damage by rodents, sawflies, or other pests were not noted in 2000.

A 27-year summary of data obtained from the continuous spring wheat and wheat-fallow systems are reported below.

Snow Moisture	Plant Height	Grain Protein	Grain Test Weight	Grain Yield
<i>Open Field Stubble</i>				
1974	20.0	15.2	60.0	26.0
1975	25.0	16.1	59.5	30.4

1999	33.1	12.6	59.0	53.8
2000	--	15.0	63.0	47.0
Average	26.1	15.2	59.1	35.2

During the past 27-year period of this continuous cropped spring wheat study, grain test weights have averaged 0.4 lbs. per bushel higher under continuous cropping. Conversely, grain protein content of wheat on fallow has averaged 0.8% higher than wheat on open field continuous cropping. Average yields for continuous crop spring wheat is 23.8 bushels per acre for open field continuous cropped spring wheat and 35.2 bushels per acre for summer fallow.

In this long-term study the continuous wheat cropping yields in the barrier system yielded 3.0 bushels per acre less than continuous wheat cropping in open field stubble. One bushel per acre of the yield difference is due to the land removed from wheat production by the presence of the barriers as this land area is included in the plot size for yield determination. The competitive effect of the tall wheatgrass in the barriers nearby wheat plants also causes some yield reduction. However, tall wheatgrass barriers do provide some benefits such as reduced wind erosion and favorable climatic effects within the barriers, which should be considered for soil and water conservation of the land. These factors become more critical in years of below normal rainfall and on soils with lower soil moisture carrying capacity.

The results of this long term study have also shown that the barrier system continuous cropping wheat generally out yields open field stubble continuous cropping wheat when yields are less than 20 bushels per acre (1977, 1980, 1984, 1985, 1989 and 1990) but that open field stubble continuous cropping wheat generally had a yield advantage over the barrier system when wheat yields exceed this level (1974, 1975, 1976, 1978, 1983, 1987, 1993, 1994, 1995, 1996, 1997, and 1998). Open field stubble continuous cropping wheat had a very definite yield advantage over the barrier system continuous cropped wheat when yields exceed 30 bushels per acre (1975, 1976, 1978, 1991, and 1992).

In 1977, no-till treatments were added to this long-term continuous cropping system for comparison with conventional till plant plots. The no-till plots have produced yield similar to conventional till and plant plots except for in 1978, 1986, and 1992 – 2000. In 1978 the no-till plots had a larger population of wild oats than conventional till and plant plots. In 1986 when the no-till plots were seeded with a no-till versatile Noble No. 2000 drill deep seed placement contributed to the lower yields in the no-till plots. In 1992 – 2000, the lower no-till yields were attributed in part to a larger population of volunteer wheatgrass in the no-till plots despite the application of Roundup herbicide in early spring of each year. A higher rate of Roundup herbicide and/or a fall application of Roundup herbicide is improving control of the volunteer tall wheatgrass. Also in 1993, poor seed to soil contact in the no-till plots resulted in delayed emergence and reduced yields and in 1997 wild oats were a problem. Test weights have been slightly higher in no-till plots whereas protein has averaged 0.8% lower in no-till plots than tilled plots despite the no-till plots' lower yield of 3.2 bushels per acre.

The incidence of the disease *Pyrenophora trichostoma* (tan spot) and *Septoria* has been highest in the no-till plots. Conversely, the incidence of annual weeds such as wild oats, green foxtail, and yellow foxtail has been usually greater in the till and plant plots with the exception of 1978, 1997, 1998, 1999 and 2000 when wild oats occurred in the no-till plots. Volunteer tall wheatgrass has been an annual problem in all the barrier plots each spring, necessitating an application of Roundup herbicide to destroy the volunteer wheatgrass prior to seeding. This treatment has been effective in controlling annual weeds that have emerged in the no-till plots prior to seeding time. Over the twenty-seven year period, continuous spring wheat cropping has produced 6.2 bushels per acre per year more than the spring wheat-fallow rotation.

* Data in 1981 were omitted as different varieties were planted in no-till and till and plant plots.

In 1988, continuous cropped wheat plots were a complete crop failure.

** Deep seed placement contributed to the lower yield of the no-till plots in 1986.

In 1998 the volunteer wheatgrass barriers were sprayed with Roundup with the purpose of eliminating the barriers. In 1999, the land that had previously been in grass barriers was planted, with half of the barrier land tilled and the other half of the barrier land planted without tillage. Spring wheat was continuously cropped with spring tillage or no tillage as done in previous years on the barrier land. Wheat samples were harvested from each treatment for yield and other performance characteristics.

Spring wheat grown on grass barrier land was taller, had greater protein content, lower test weight, and greater yield than the long-term continuously cropped wheat. Continuously cropped spring wheat with spring tillage had greater yield than continuously cropped spring wheat no tillage. Differences in tillage treatments were also detected in wheat grown on grass barrier land. Wheat following grass that had been tilled had significantly greater yield and protein content, and significantly lower test weight than wheat following grass that had not been tilled.

COMPARISON OF WHEAT GROWN ON BARRIER LAND TO LONG-TERM CONTINUOUS CROPPED WHEAT

Description	Tillage	Height in	Grain Protein %	Test Weight lb/bu	Yield bu/acre
Continuously cropped since 1974	No-till	28a	9.4a	63.1a	32.2a
Continuously cropped since 1974	Spring-till	28a	9.7a	63.4a	41.7 b

Crop/fallow	Black fallow	33 b	12.6 c	62.1 b	54.5 c

Data analyzed using t-tests

FUTURE PLANS:

Future plans of this long-term study will include investigating the influences of the grass barriers on wheat production within the area previously occupied by the barriers. The long-term influences of no-till, conventional till, and continuous cropping on wheat growth, vigor, yield, quality and other crop performance characteristics is a long-term objective that will continue. Continuation of this long-term study could include detailed soils analyses to determine the long-term influence of no-till, conventional till, and continuous cropping on soil health. It may also prove beneficial to assay the soils of the continuous cropping wheat plots for potential biocontrol agents for wheat diseases and / or other wheat pests.
